

R&D Webinar - NESTORE Project Outcomes | 26/05/2026

Towards cumulative impact assessment of offshore wind farms

Uncertainties in models: Accounting for uncertainties in OWF impact assessment using ecosystem models.

Speaker: Raphaël Girardin (Ifremer)

WP4 Leader: Ghassen Halouani (Ifremer)

Main contributor: Yansong Huang (FEM)

PhD Director: Frida Lasram (ULCO, IFSEA)

Diversity of OFW effects on marine ecosystem

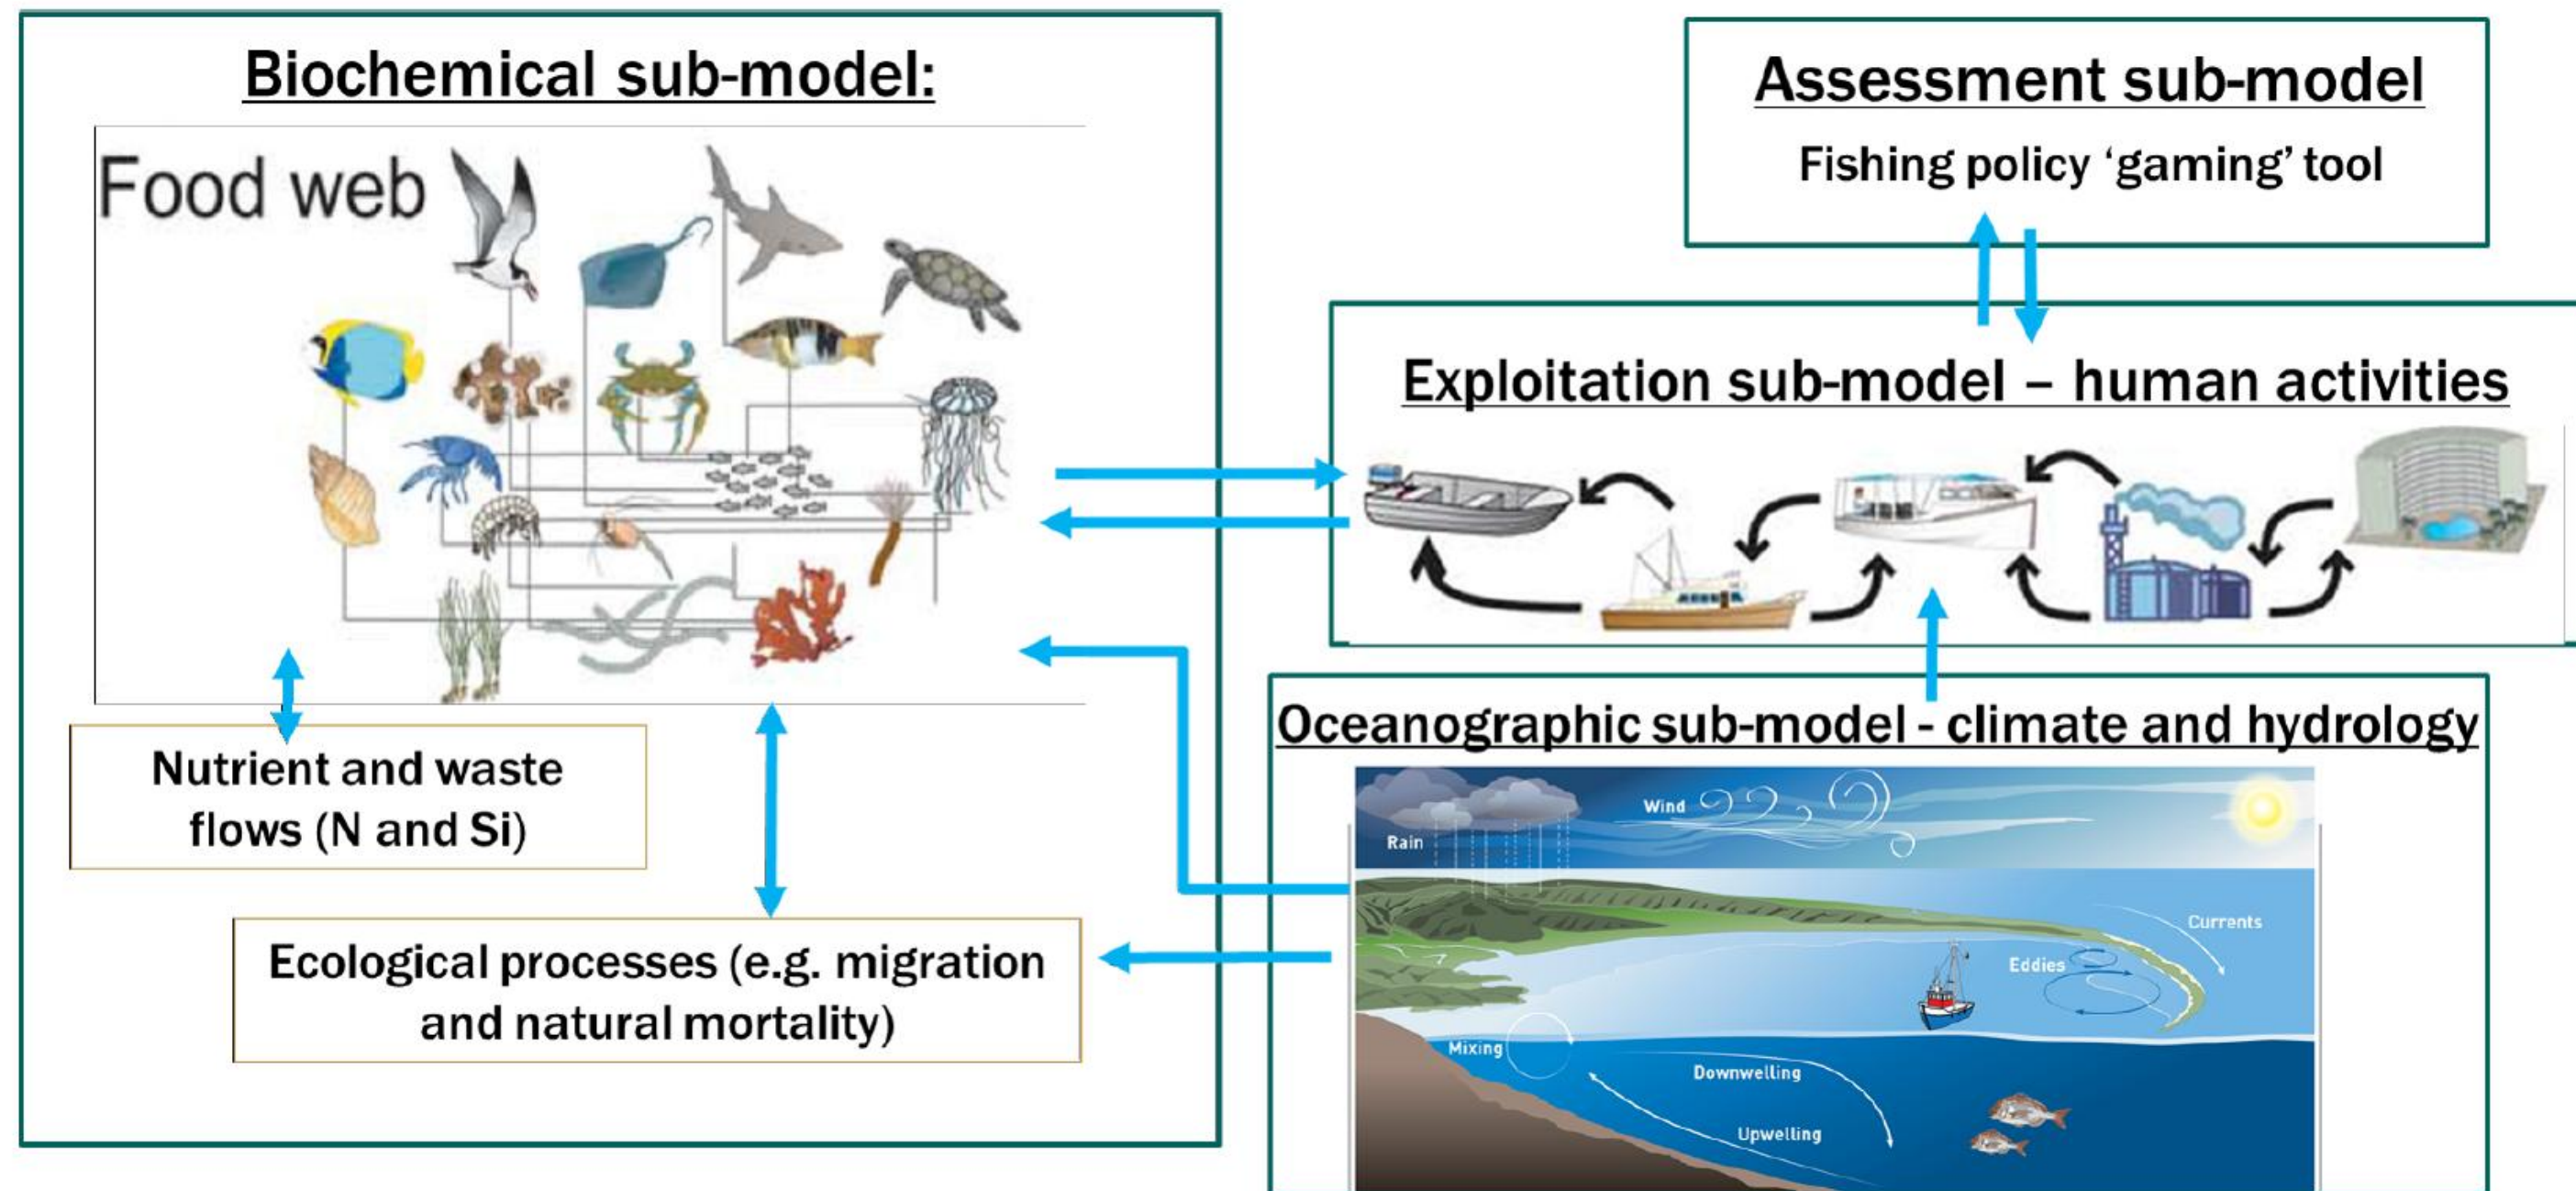

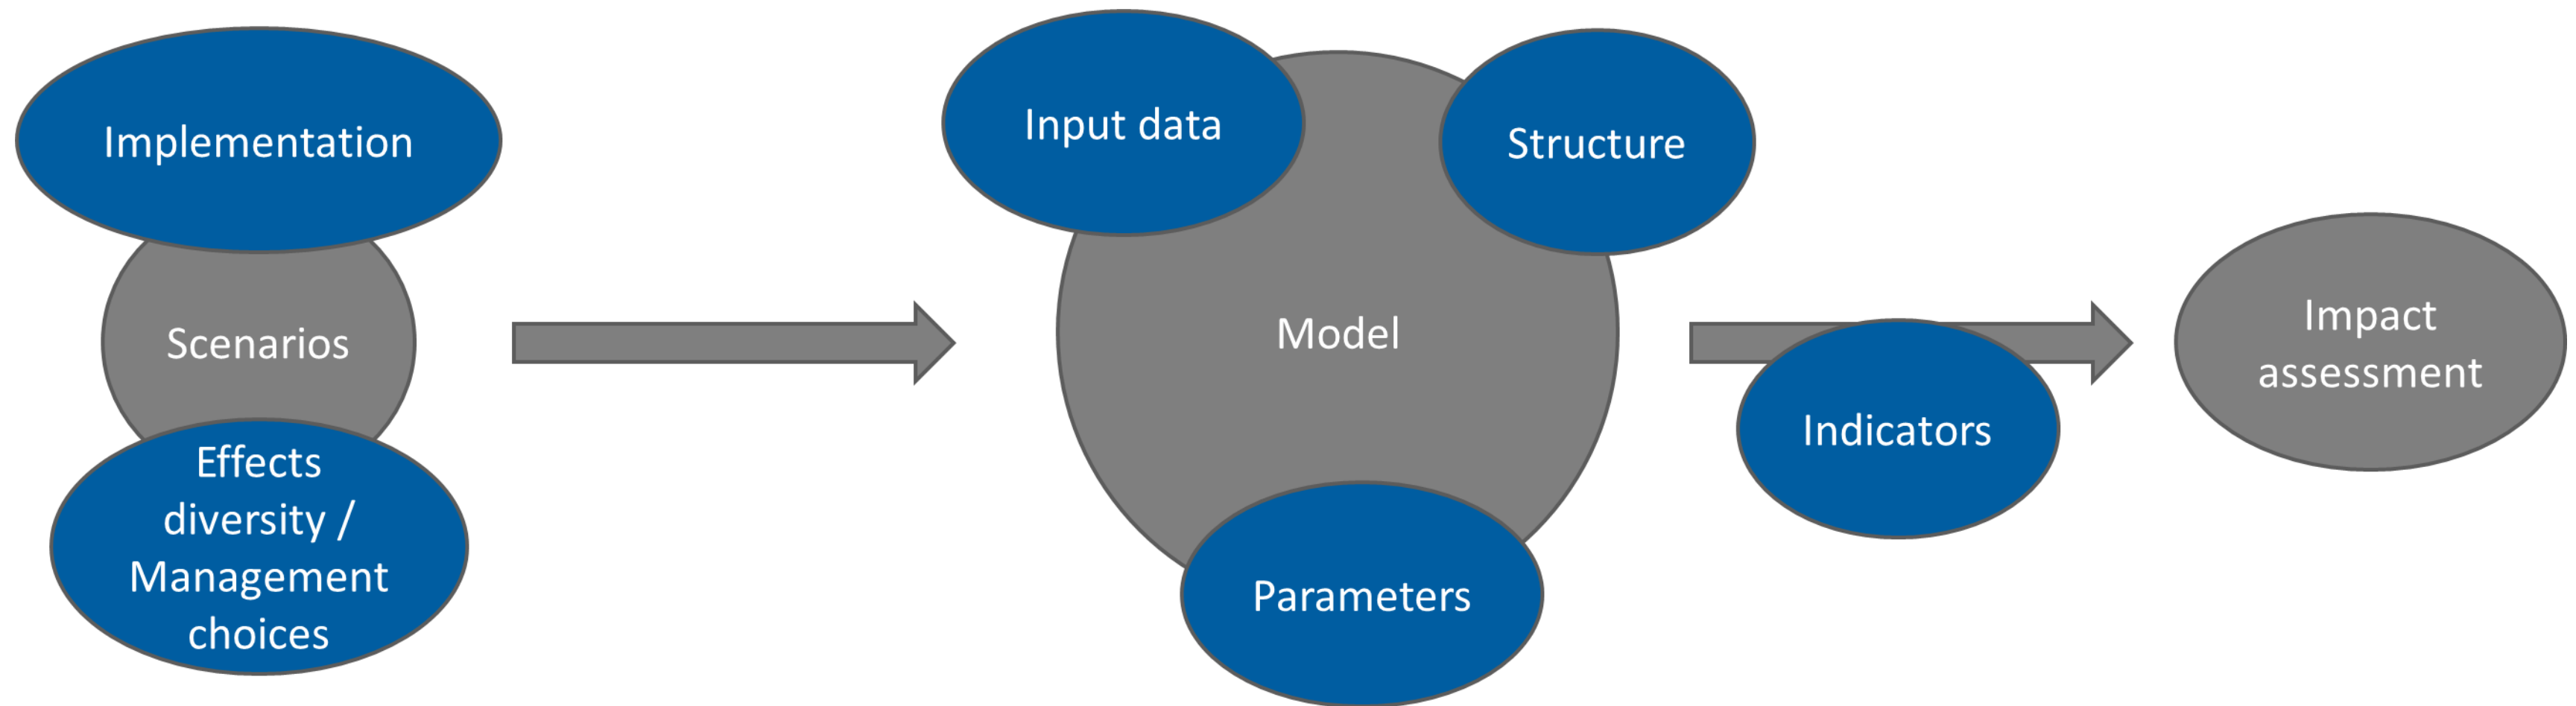

- | | | | |
|--|--|--|--|
|  Habitat changes |  Collision |  Light emission |  New species introduction |
|  Turbidity |  Entanglement |  Noise emission |  Disturbance |
|  Temperature modification |  Movement restriction |  EMF emission |  Pollution |

Marine ecosystem model and human impact assessment

« Managing and understanding complex system require complex tools adapted to system complexity »
(Ashby 1956, An Introduction to Cybernetics)

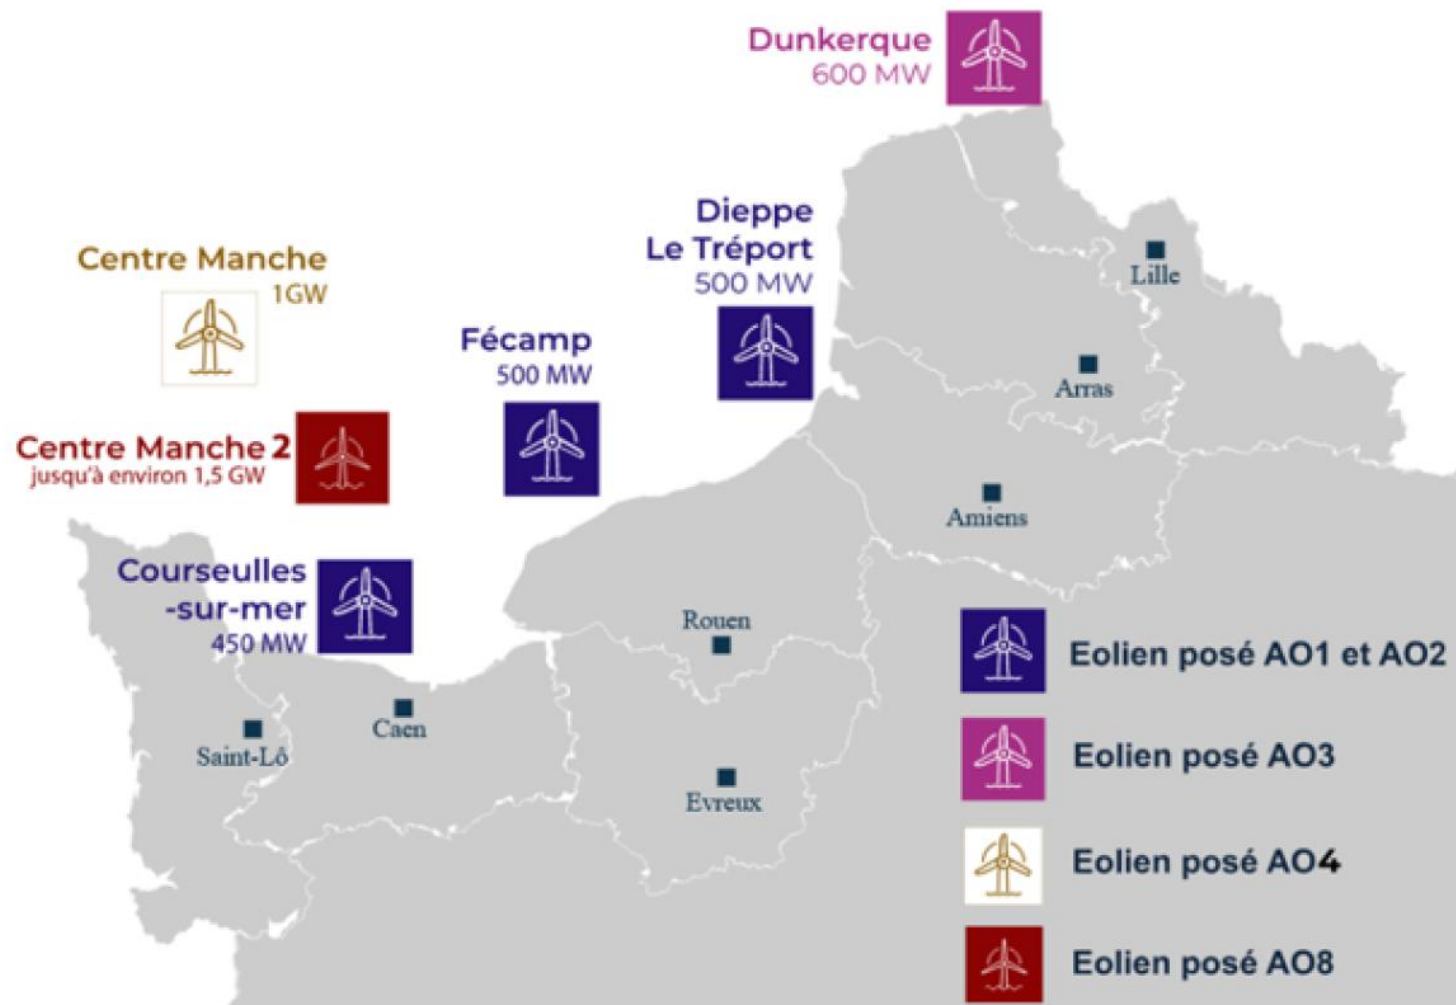

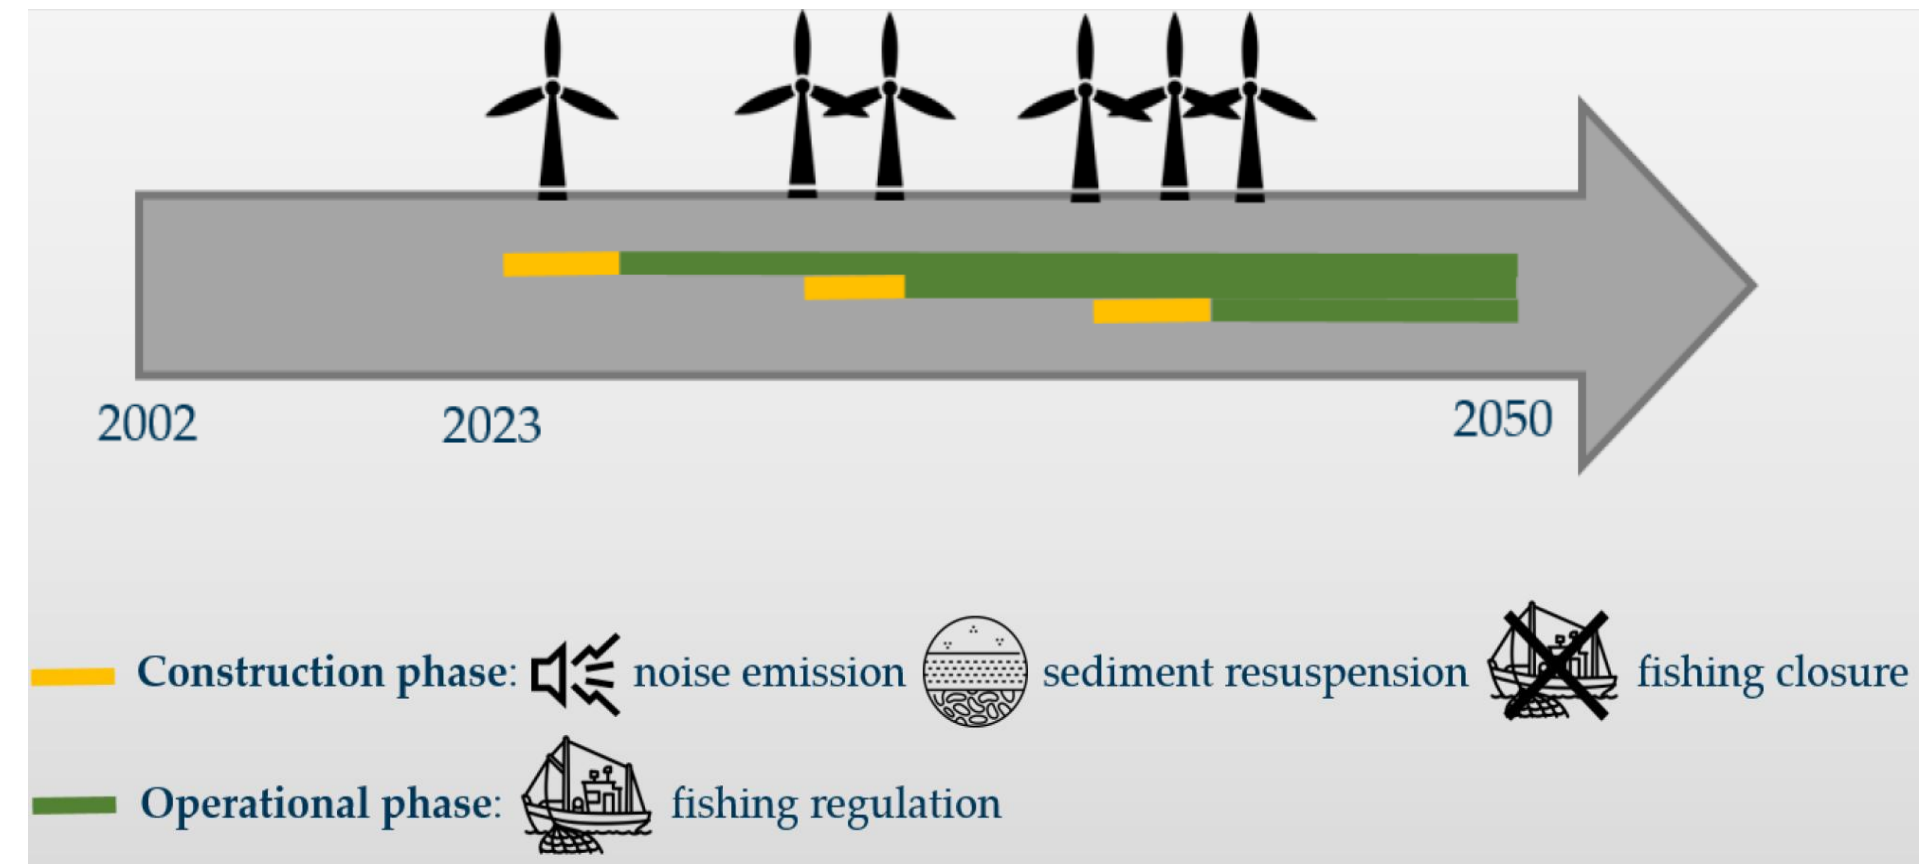

Sources of uncertainties in impact assessment modeling

OWF impact assessment in the Eastern English Channel (EEC) accounting for several effects & OWF life cycle

©Éolienne en mer en France

OWF deployment scenarios¹

Energy cost efficiency

Outside protected areas

Distance from shore

Balance

Fishing scenarios within OWF during operational phase

No restriction

Closed to active gear

No Fishing

Compare ecosystem modeling approaches applied in the Eastern English channel

OSMOSE¹

Ecospace²

	OSMOSE ¹	Ecospace ²
Main Hypothesis	IBM & opportunistic predation	Mass and energy conservation
Group definition	Super-individuals (Fish school)	Species or functional groups
Spatial coverage	Eastern English channel	Eastern English channel & southern North Sea
Calibration period	2002-2021	2006-2018
Biological groups	Fish, cephalopods, planktons and benthos	Fish, cephalopods, planktons, benthos, birds, and mammals
Fishing fleets	4	8
Species movement within distribution area	Stochastics	Biology, predation and habitat preference

OWF impact assessment and scenario uncertainties

OWF impact assessment and scenario uncertainties

OWF impact assessment and structural uncertainties

- 195 parameters governing growth, predation, mortalities, fishing
- $\pm 20\%$ Perturbation with 8 values per parameter

$\sim 10^{172}$ years of simulation
(Universe ~ 1.4 billion years)

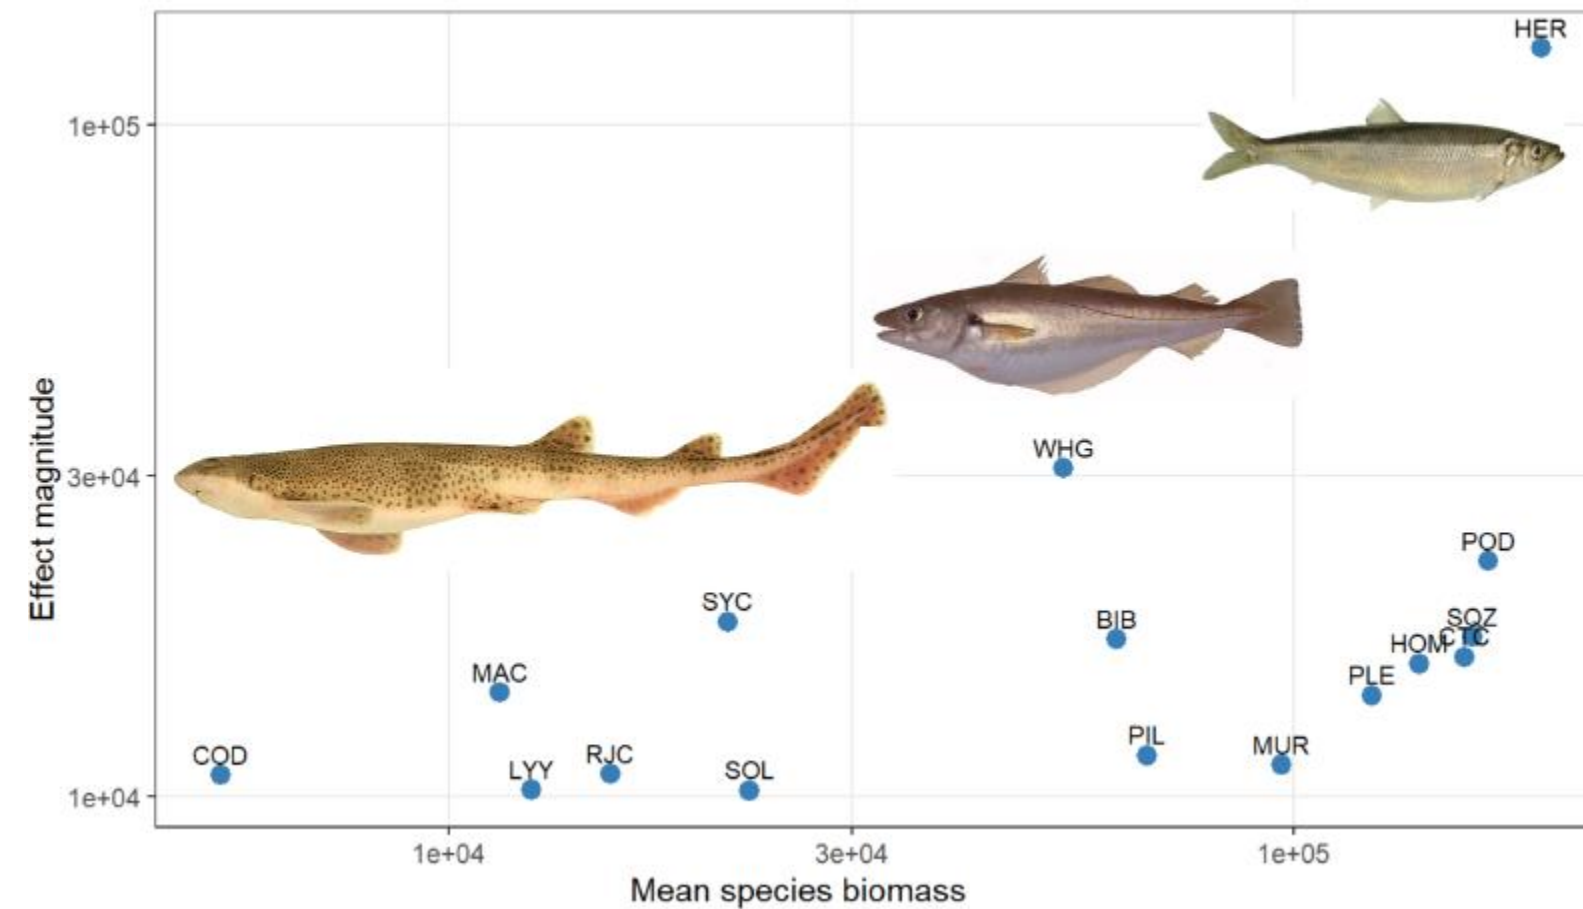

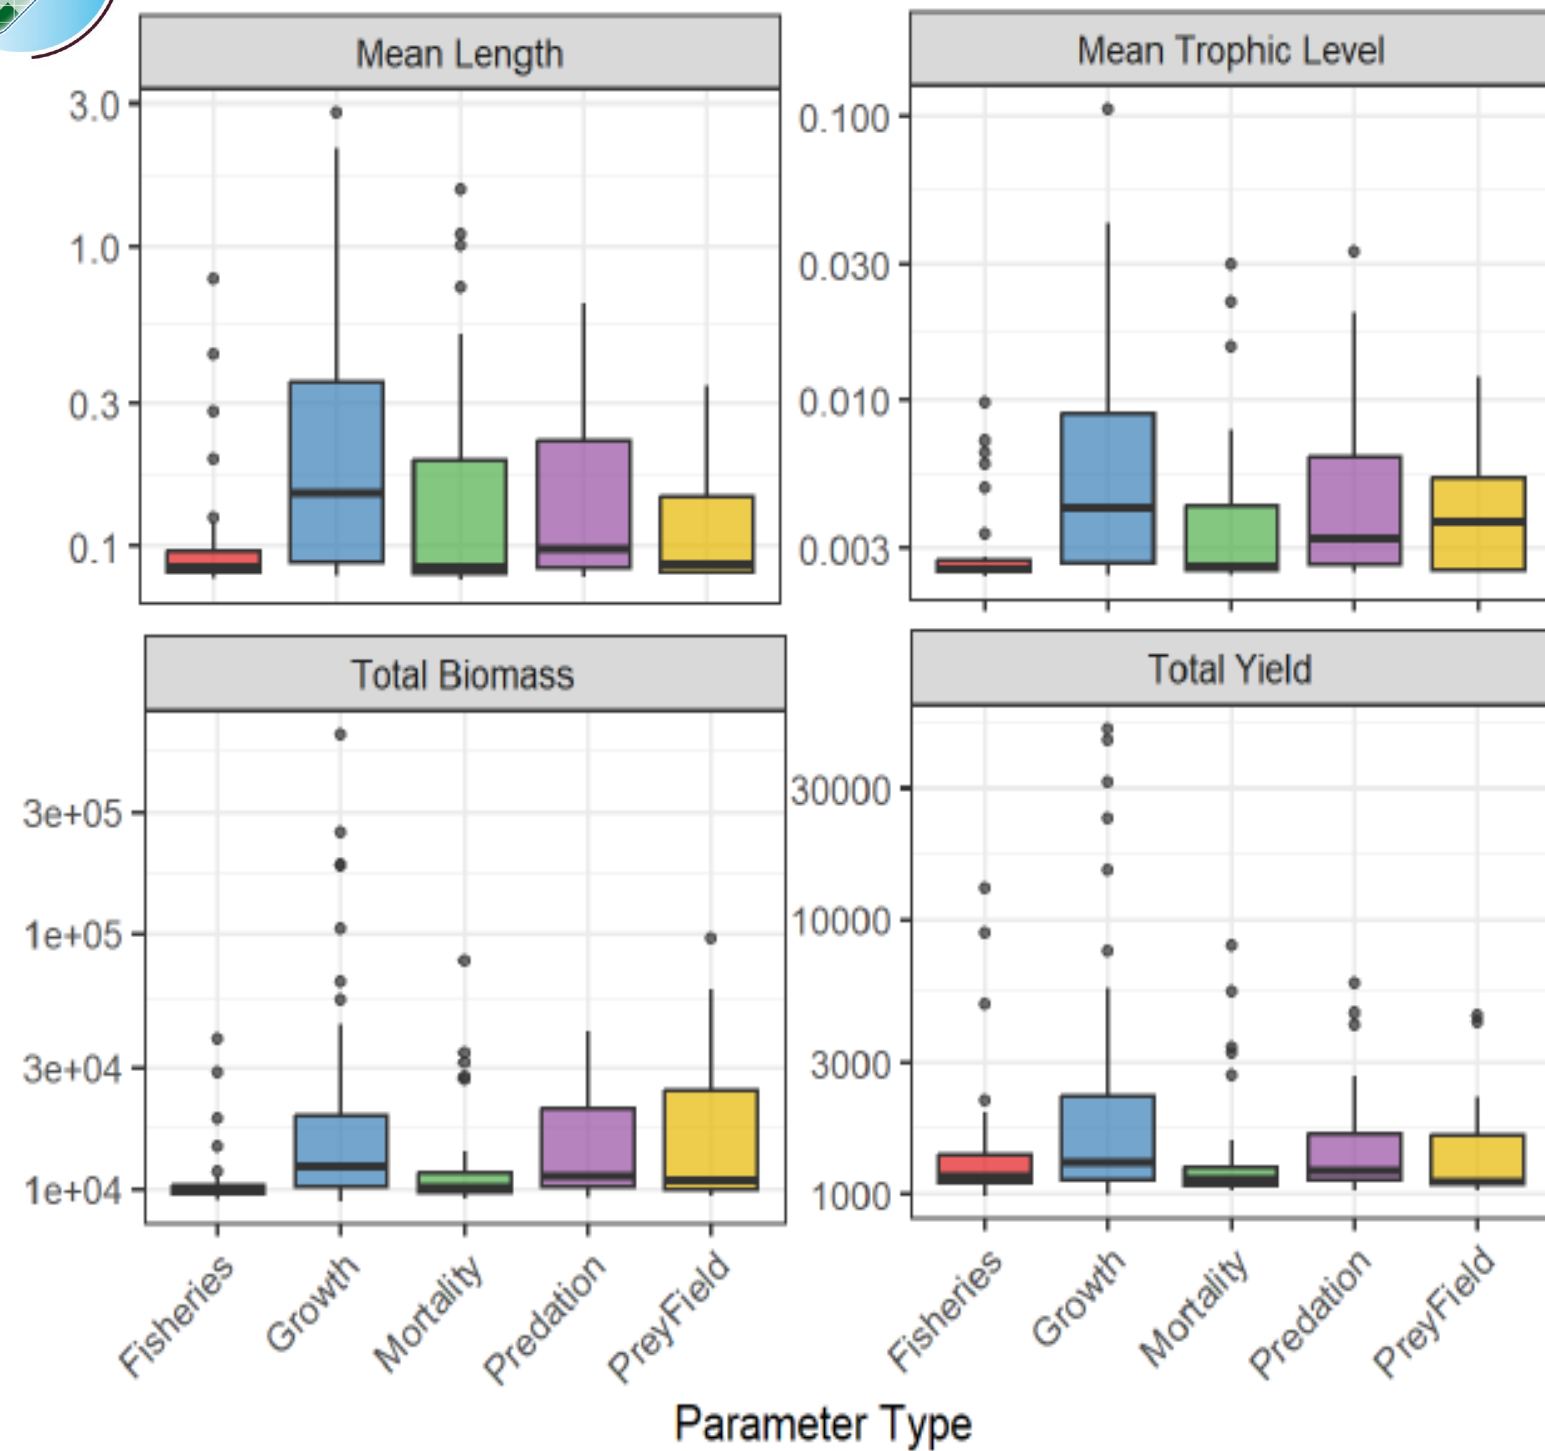

Morris OAT Factorial Plan :
2 million simulations

$\sim 2-3$ weeks of simulation
on DATARMOR

Parameter sensitivity magnitude in OSMOSE EEC

Common name	FAO code
Lesser spotted dogfish	SYC
Striped red mullet	MUR
Pouting	BIB
Whiting	WHG
Poor cod	POD
Cod	COD
Dragonet	LYY
Sole	SOL
Plaice	PLE
Seabream	HOM
Mackerel	MAC
Herring	HER
Pilchard	PIL
Squid	SQZ
Cuttlefish	CTC
Thornback ray	RJC

- Overall effects of noise emission and sediment resuspension implemented through species displacement might lead to a small decrease of biomass
- Fishing closure within OFW during operational phase could compensate part of the decrease in biomass BUT at a greater loss (in tonnage) for the fishing sector.
- Model structure uncertainty leads to more or less persistent impact of the construction phase through time (OSMOSE vs Ecospace hypothesis)
- OFW effect affecting growth, herring, whiting and/or Lesser spotted dogfish are most likely to have an impact in OSMOSE EEC

- Development of models is required to properly account for other effects of OWF (Hydrodynamic, biogeochemical cycle, habitat or fishing behaviour modification)
- Outcomes of the sensitivity analysis could tailor full uncertainty propagation analyses
- Propagation of uncertainties will allow for risk assessment in management strategy evaluation

Beyond NESTORE consortium a special thanks to Ricardo Oliveros-Ramos, Nicolas Barrier, Criscely Luján, Morgane Travers-Trolet, Antoine Quennevat, Marie Savina-Rolland, Alexei Sentchev for their inputs and works, IFSEA graduate school for additional funding and ICES, Ifremer SIH and Flotte Océanographique Française for data provisions.

Thank you for your attention!
